

AKS Provisioning using Terraform

- We will provision the AKS using Terraform as an Infrastructure as Code.
 - We will deploy it in a custom Virtual Network for isolation.
 - We will connect the AKS to ACR for Docker Image.
 - We will also deploy MySQL Flexible to store the relational data and connect it to AKS.
-

Prerequisites

1. Azure Account with Subscription.
 2. Terraform installed.
 3. Kubectl installed.
-

Steps

1. Create the **aks-terraform** directory.
2. The folder structure for the above-created directory is as follows:

```
aks-terraform
├── .terraform.lock.hcl
├── locals.tf
├── main.tf
├── outputs.tf
├── providers.tf
├── terraform.tfstate
├── terraform.tfstate.backup
└── .terraform
```

We need to only create *providers.tf*, *main.tf*, *outputs.tf*, & *locals.tf* file. Other files are generated while initiating terraform.

3. Create a *providers.tf* file inside the above-created directory.
4. Inside it, define the following:
 - terraform
 - required_providers
 - provider
 - azurerm
5. Click [code](#) for reference.
6. The definition of *providers.tf* file is complete.
7. Now, create the *main.tf* file.
8. Inside *main.tf* file, we will use the following predefined modules:
 - resource-group
 - virtual-network
 - acr

- mysql-flexible
 - aks
9. Click [code](#) for reference.
 10. The definition of *main.tf* file is complete.
 11. Now we will create *outputs.tf* file.
 12. Inside it, define the following outputs.
 - acr-login-server
 - acr-admin-username
 - acr-admin-password
 - DB_HOST
 13. Click [code](#) for reference.
 14. The definition of *outputs.tf* file is complete.
 15. Now we will create *locals.tf* file.
 16. Inside it, define the following variables:
 - resource-group-properties
 - virtual-network-properties
 - acr-properties
 - mysql-flexible-properties
 - aks-properties
 17. Click [code](#) for reference.
 18. The definition of *locals.tf* file is complete.

Ensure you give the appropriate values to the variables defined in *locals.tf* file.

Provisioning the Infrastructure

Now we will provision the Azure infrastructure by applying the above-created configuration files.

Ensure Azure CLI is configured with appropriate Azure Account credentials with enough permissions.

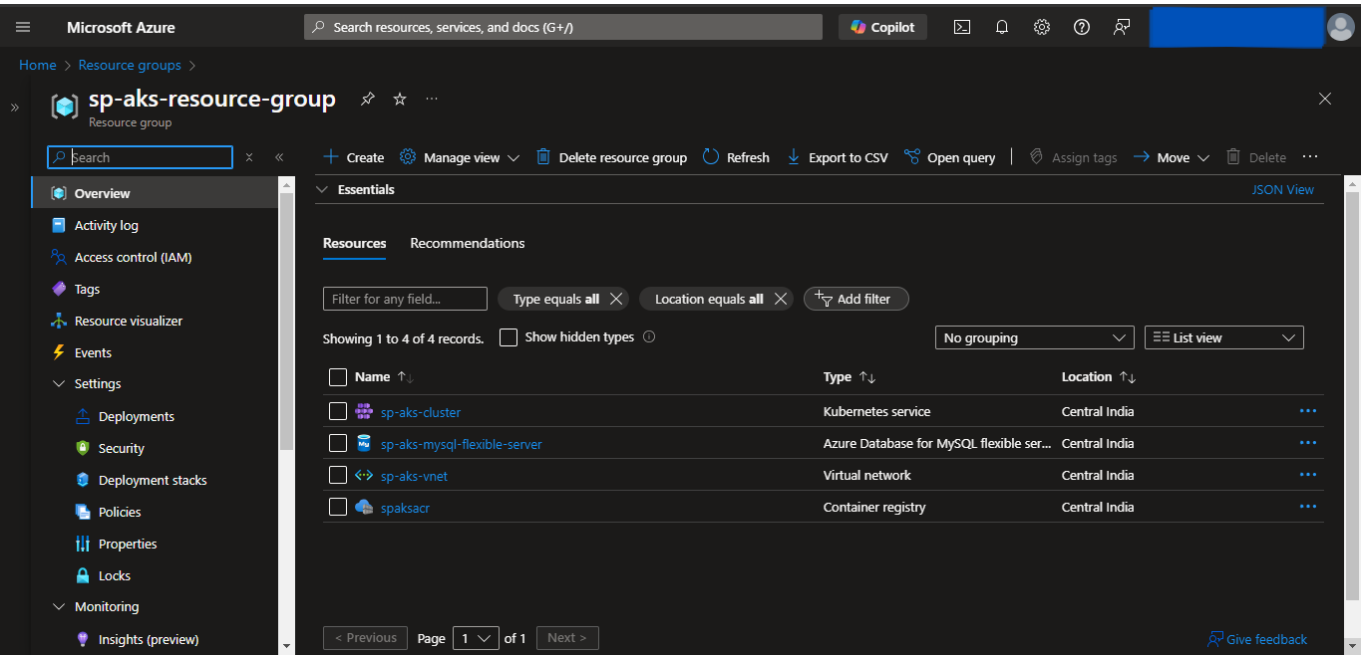

Also first provision the ACR, push the Docker Image, and then provision the Container App. To do that, comment out the **aks** module and follow the further steps.

Steps:

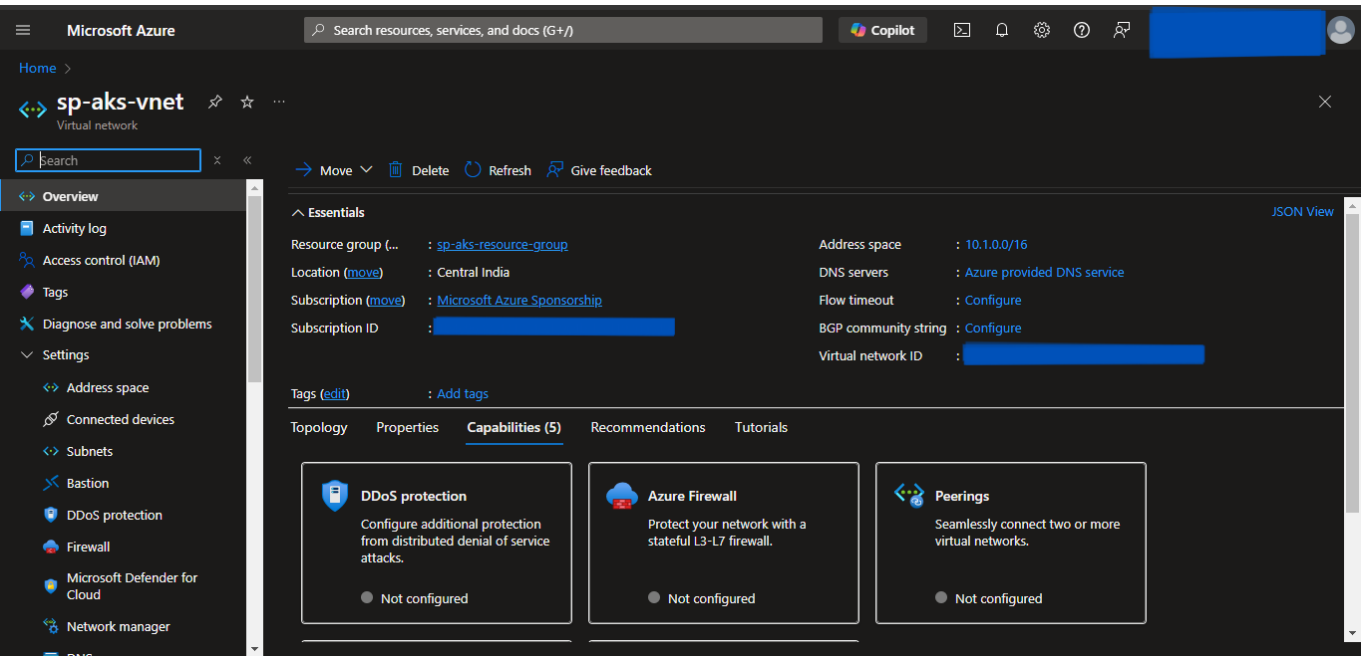

1. Open the PowerShell.
 2. Change the directory to the above-created **aks-terraform** directory using **cd** command.
 3. Run the **terraform fmt -recursive** command to format the syntax of the files.
 4. Run the **terraform init** command to initialize the *terraform*.
 5. Run the **terraform validate** command to validate the configuration files.
 6. Run the **terraform plan** command to plan the resources to be created.
 7. Run the **terraform apply** command and if prompted, type **yes** to provision the infrastructure.
 8. Run the **terraform output** command to get the values of defined variables in *outputs.tf* file.
 9. Head to the Azure Console, and verify the created resources.
-

Screenshots of Provisioned Infrastructure

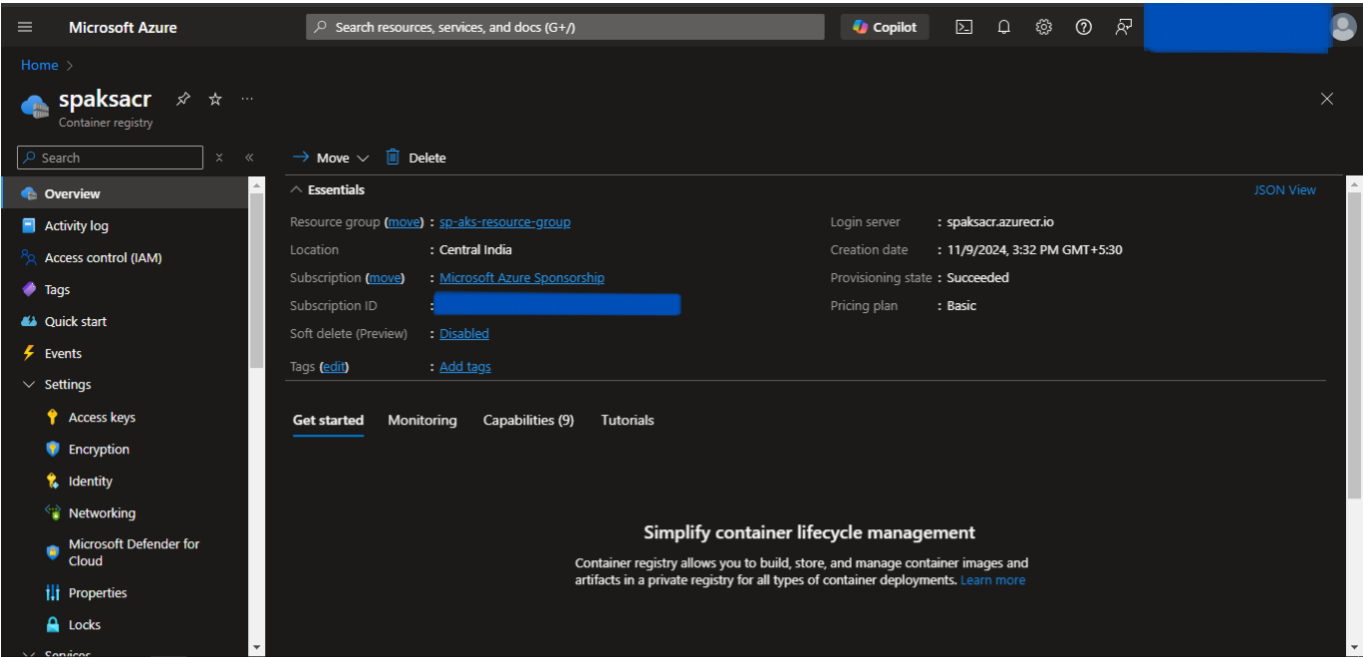

Resource Group Image

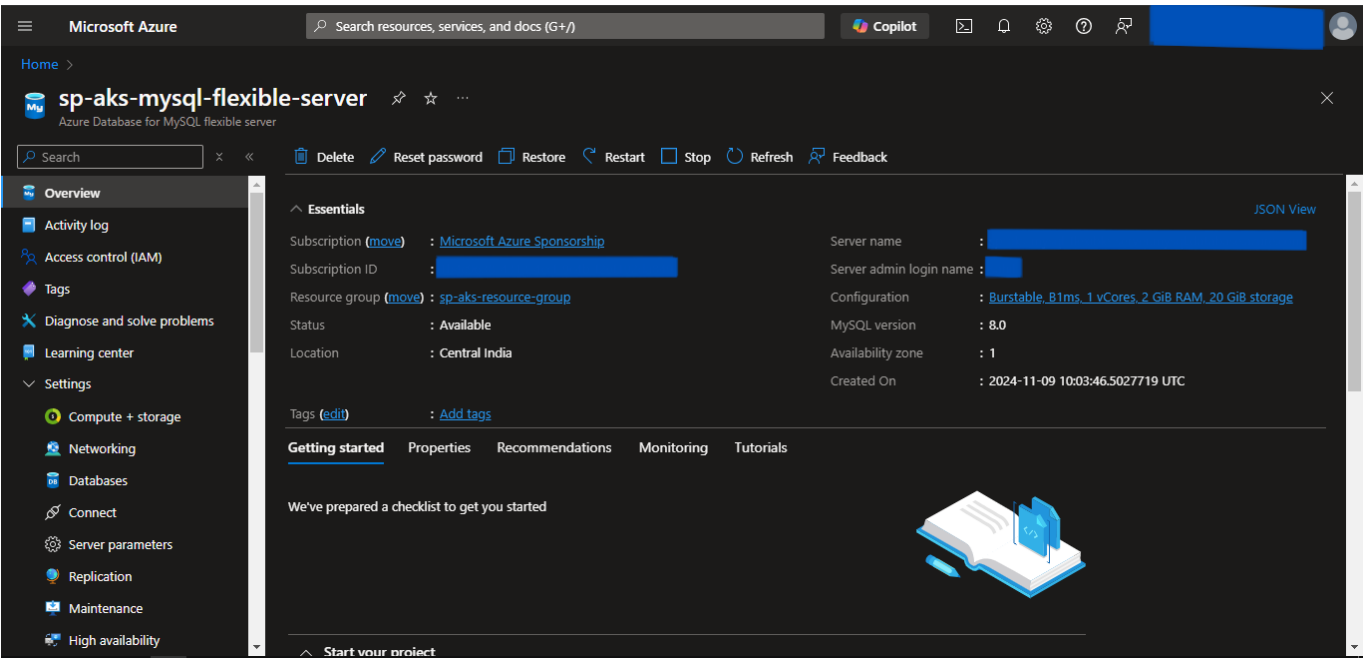

Virtual Network Image

ACR Image

MySQL Flexible Server Image

Now push the Docker Image to ACR

1. Open a new Powershell window.
2. Run the following commands to log into ACR:
 - `az login`
 - `az acr login --name "acr-name"`
3. Then tag & push the docker image using the following commands:
 - `docker tag "image-name:tag" "acr-name".azurecr.io/"image-name:tag"`
 - `docker push "acr-name".azurecr.io/"image-name:tag"`

Substitute *acr-name* with the value defined in the above-created locals.tf file. Also, substitute *image-name:tag* with its respective name.

Provisioning the AKS

Uncomment the **aks** module that we commented on earlier and follow the further steps.

Steps:

1. Open the Powershell Window.
2. Run the `terraform fmt -recursive` command to format the syntax of the files.
3. Run the `terraform init` command to initialize the *terraform*.
4. Run the `terraform validate` command to validate the configuration files.
5. Run the `terraform plan` command to plan the resources to be created.
6. Run the `terraform apply` command and if prompted, type **yes** to provision the infrastructure.
7. Once completed, head to the Azure Console, and verify the created resources.
8. Run the `terraform output` command to get the values of defined variables in *outputs.tf* file.

AKS Image

The screenshot displays the Microsoft Azure portal interface for a Kubernetes service named 'sp-aks-cluster'. The left sidebar shows the navigation menu with 'Overview' selected. The main content area is divided into two sections: 'Essentials' and 'Properties'.

Essentials:

- Resource group: [sp-aks-resource-group](#)
- Power state: Running
- Cluster operation st...: Succeeded
- Subscription: [Microsoft Azure Sponsorship](#)
- Location: Central India
- Subscription ID: [Redacted]
- Tags: [Add tags](#)

Properties:

- Kubernetes version: 1.30.1
- API server address: [Redacted]
- Network configurati...: kubenet
- Node pools: 2 node pools
- Container registries: [Attach a registry](#)

Networking:

- API server address: [Redacted]
- Network configuration: kubenet
- Pod CIDR: 10.244.0.0/16
- Service CIDR: 10.0.0.0/16

Connect to the AKS Cluster from Powershell

1. Open a new Powershell window.
 2. Run the following commands to configure local kubectl with aks cluster:
 - `az login`
 - `az account set --subscription "subscription-id"`
 - `az aks get-credentials --resource-group "resource-group-name" --name "cluster-name" --overwrite-existing`
Substitute *subscription-id* which can be found by running `az account list` in the *id* field. Also, substitute *resource-group-name* and *cluster-name* with the values defined in the above-created locals.tf file.
 3. Now apply the Kubernetes manifest files of the application using the following command:
 - `kubectl apply -f "file-path"`
Substitute *file-path* with the Kubernetes manifest file path.
 4. To list them all, run `kubectl get all`.
 5. If a Load Balancer type Service is present then try accessing the External IP of that service in the browser.
-

Destroy the provisioned infrastructure

1. Firstly, delete all the Kubernetes Deployments using:
 - `kubectl delete -f "file-path"`
Substitute *file-path* with the Kubernetes manifest file path.
 2. To destroy infrastructure, change the directory to the above-created **aks-terraform** directory using the `cd` command.
 3. Run `terraform destroy` & if prompted, type **yes**.
 4. Infrastructure will be destroyed.
-
